Since the widespread adoption of the Internet the world has changed irrevocably for computer systems -- no longer can applications be built in a stand-alone fashion, working in private. Even though there are countless private sub-domains protected by firewalls, the Internet is an inherently public environment and software should be expected to operate in the open, as it were. This brings enormous opportunities to use the interconnectedness between applications to enhance their power.

Go! is a multi-paradigm language -- it has a strong foundation in object oriented programming, functional programming and procedural programming as well as logic programming. In addition, it is a multi-threaded language with communication capabilities. This is a powerful combination aiming to solve the hard issues of complex software development.

The aim of this book is to introduce the programmer to the features of Go! and to programming in the language.
